

## A Summary of Confidence Interval Formulas for One Sample

Name	Formula	Conditions or Assumptions
One-proportion z interval	$\hat{p} \pm z^* \sqrt{\frac{\hat{p}(1 - \hat{p})}{n}}$	<ol style="list-style-type: none"> <li>1. SRS</li> <li>2. <math>n\hat{p} \geq 10</math> and <math>n\hat{q} \geq 10</math></li> <li>3. Population is at least 10 times n</li> </ol>
One-sample t interval	$\bar{x} \pm t^* \frac{s}{\sqrt{n}}$	<ol style="list-style-type: none"> <li>1. Normal population OR <math>n &gt; 30</math></li> <li>2. <math>\sigma</math> unknown</li> <li>3. SRS</li> </ol>
One-sample z interval	$\bar{x} \pm z^* \frac{\sigma}{\sqrt{n}}$	<ol style="list-style-type: none"> <li>1. SRS</li> <li>2. Normal population OR <math>n &gt; 30</math></li> <li>3. <math>\sigma</math> known</li> </ol>

How do we know if a sample is normal?

If  $n < 10$  graph a dotplot and check for outliers and symmetry.

If  $n \geq 10$ , the options are:

- Graph a boxplot and look for symmetry and outliers. Make sure the whiskers are not too long.
- Graph a normal probability plot. The more normal a dataset, the straighter the plot.
